

# Oxygenation:

## From atmosphere to veins

Prof. Michael Veltman

MBBS FANZCA FASE FFPMANZCA

Deputy Director of Medical Services  
Director Of Anaesthesia  
Joondalup Health Campus

Adj. Professor Curtin & Notre Dame University

# Oxygenation Outline

- Physiology
- Assessment of oxygenation
- Oxygen Flux equations
- Examples

# Physiology

# Outline

- Commonly used terms
  - Oxygen Partial Pressure
  - Oxygen Saturation
  - Oxygen Content
- Oxygen Carriage in blood
- Relationship of  $SaO_2$  to  $PaO_2$
- Oxygen Cascade
- Examples

**Definitions  
and  
Common Terms**

# Oxygen Partial Pressure

- The pressure of the oxygen component of a gas or liquid
- Oxygen in air: 21%
- Total atmospheric pressure: 760 mmHg
- Pressure of O<sub>2</sub> in atmosphere: 159 mmHg

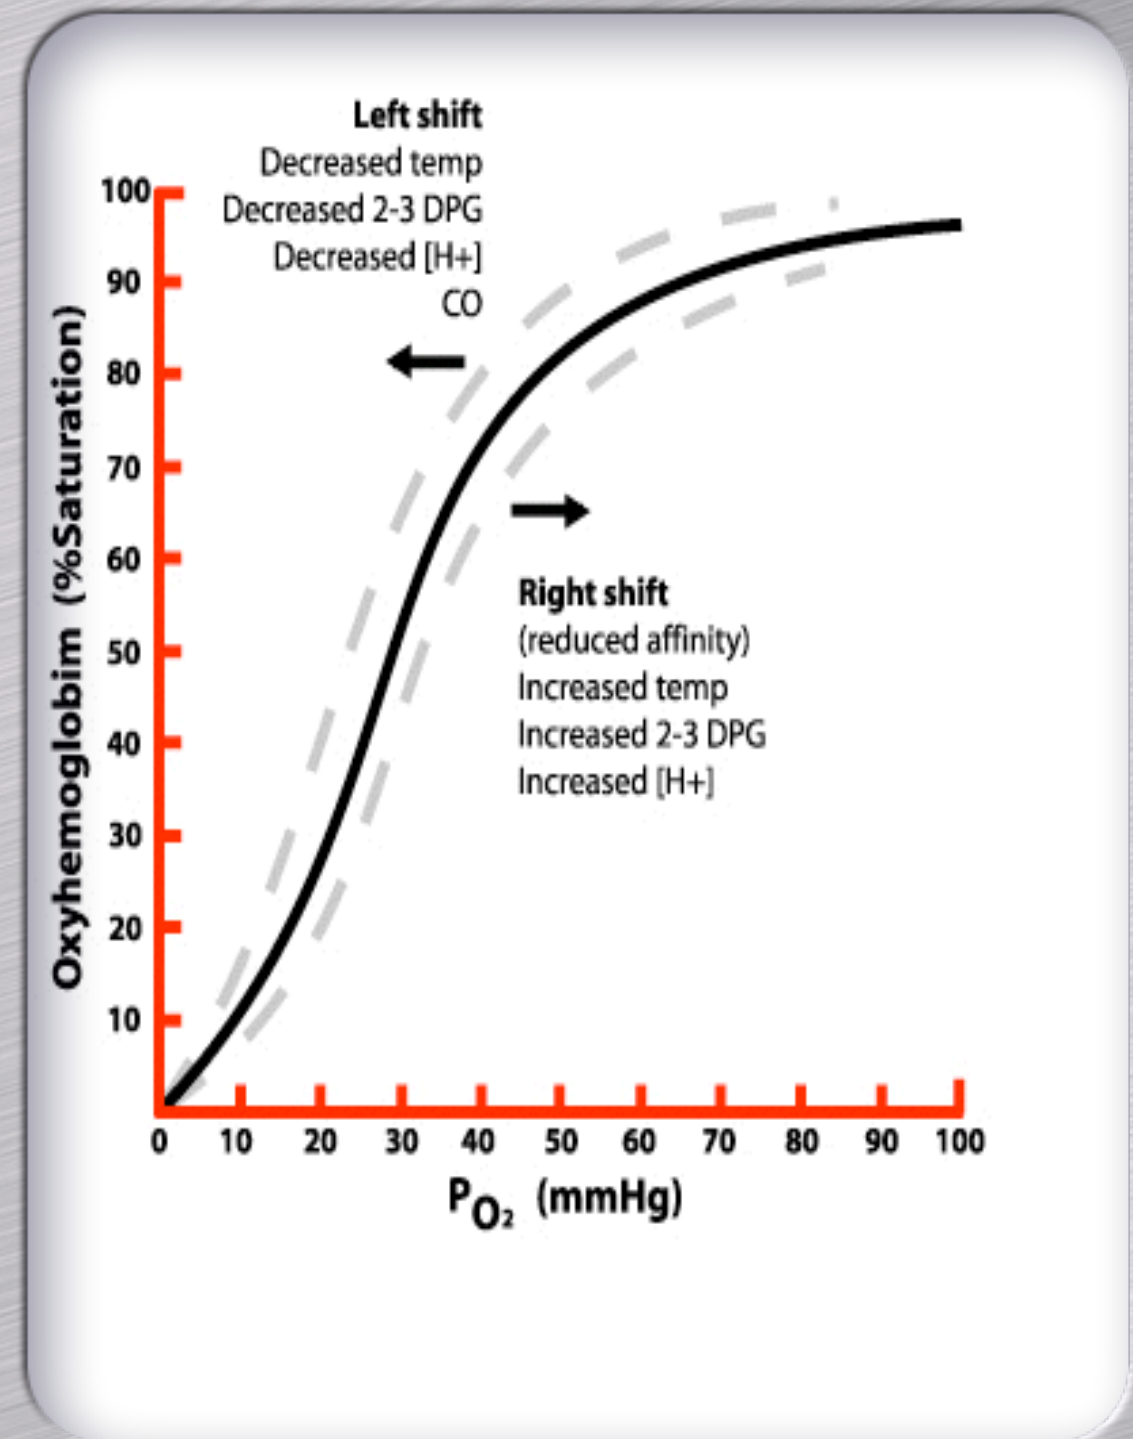

# Oxygen Saturation

- This is the percentage of haemoglobin that carries oxygen
- Normally quite high (> 95%)
- Difference between an ABG and an oximeter
  - SaO<sub>2</sub> – From a blood gas machine
  - SpO<sub>2</sub> – From an oximeter

# Dissociation curve

- Changes with:
  - ↑ Acidosis
  - ↑ Warmth
  - ↑ Carbon dioxide
- Chronically with:
  - ↑ 2,3 DPG levels

# Oxygen Carriage

# Oxygen Content

- Where is oxygen stored in the blood?
  - Directly in blood as a gas in solution
  - On Haemoglobin
- $\text{CaO}_2$  is the oxygen content of blood
  - Expressed in ml oxygen per litre blood

# On Haemaglobin

# Directly in Plasma

- Small amount stored on plasma.
- PaO<sub>2</sub> \* 0.03

# Oxygen Storage

- Oxygen storage in blood equals
  - Oxygen stored on Hb
  - PLUS
  - Oxygen dissolved in blood

$$SaO_2 \cdot Hb \cdot 1.34 + PaO_2 \cdot 0.03$$

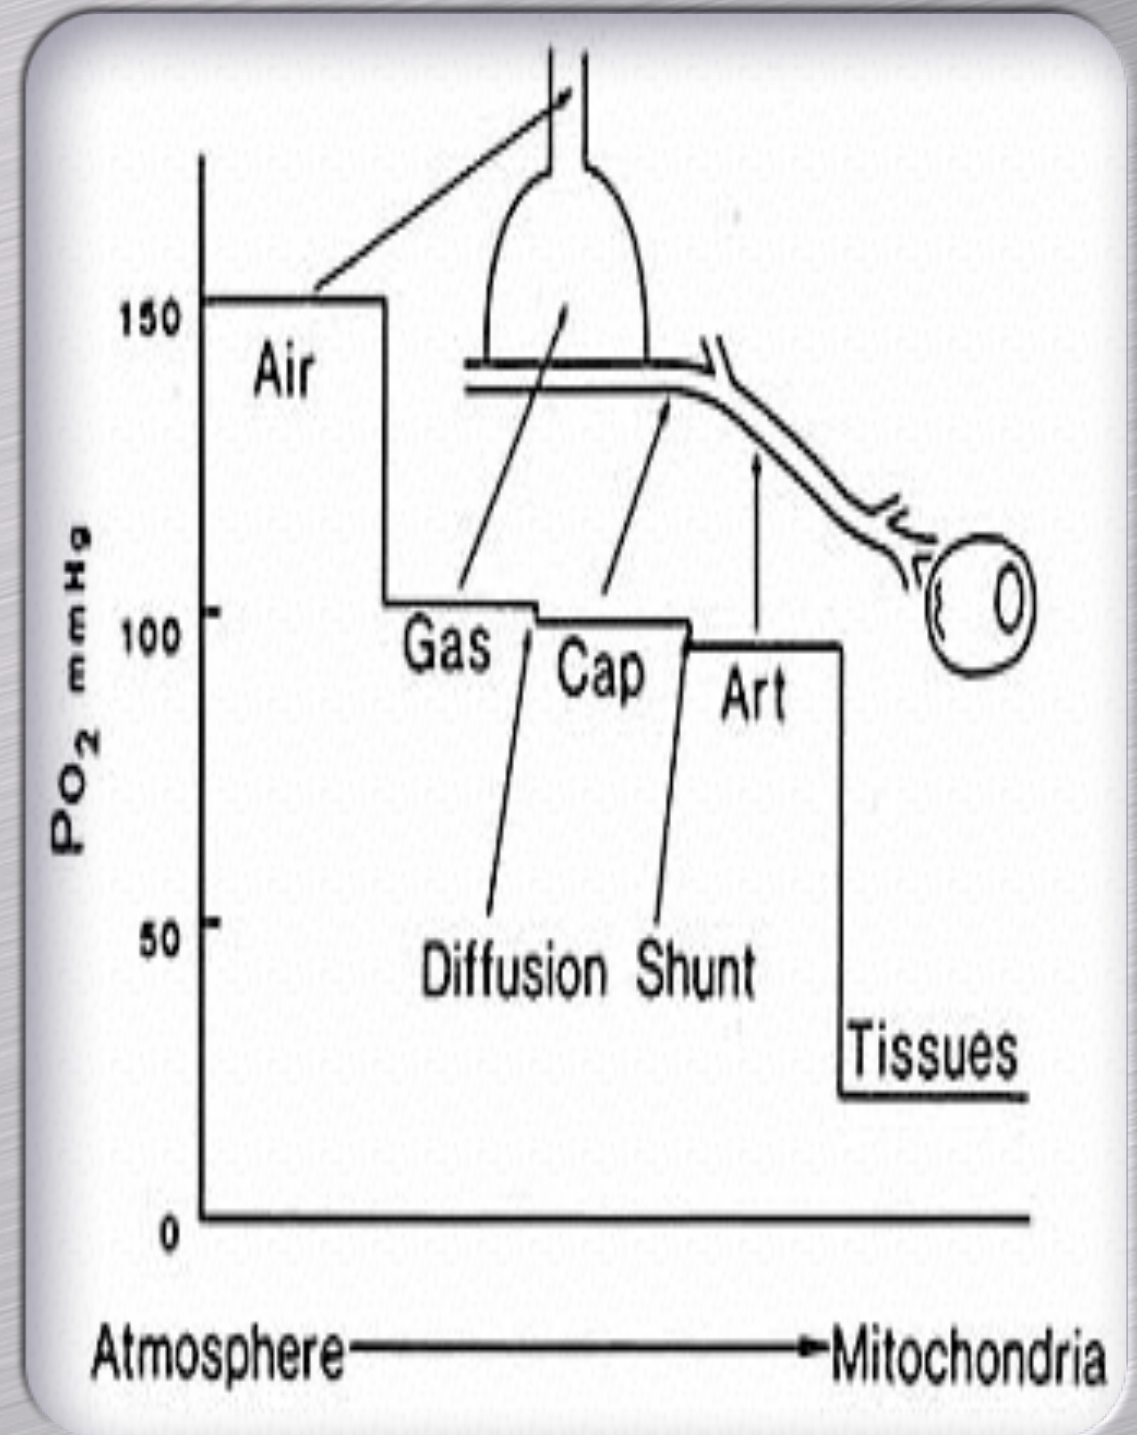

# Oxygen Cascade

# Oxygen Cascade

- Normal inspired Oxygen is 160 mmHg
- Pressure falls by:
  - Humidification
  - Mixing with  $\text{CO}_2$
  - Diffusion
  - Shunt
- Before entering tissues

# Air

- Atmospheric pressure is 760 mmHg
- 21% of this is  $O_2$
- $PO_2 = 160$  mmHg

# Humidification

- Air is warmed and humidified in airways.
- $P_{\text{Water}}$  at body temperature is 47 mmHg
- $PO_2 = 150$  mmHg

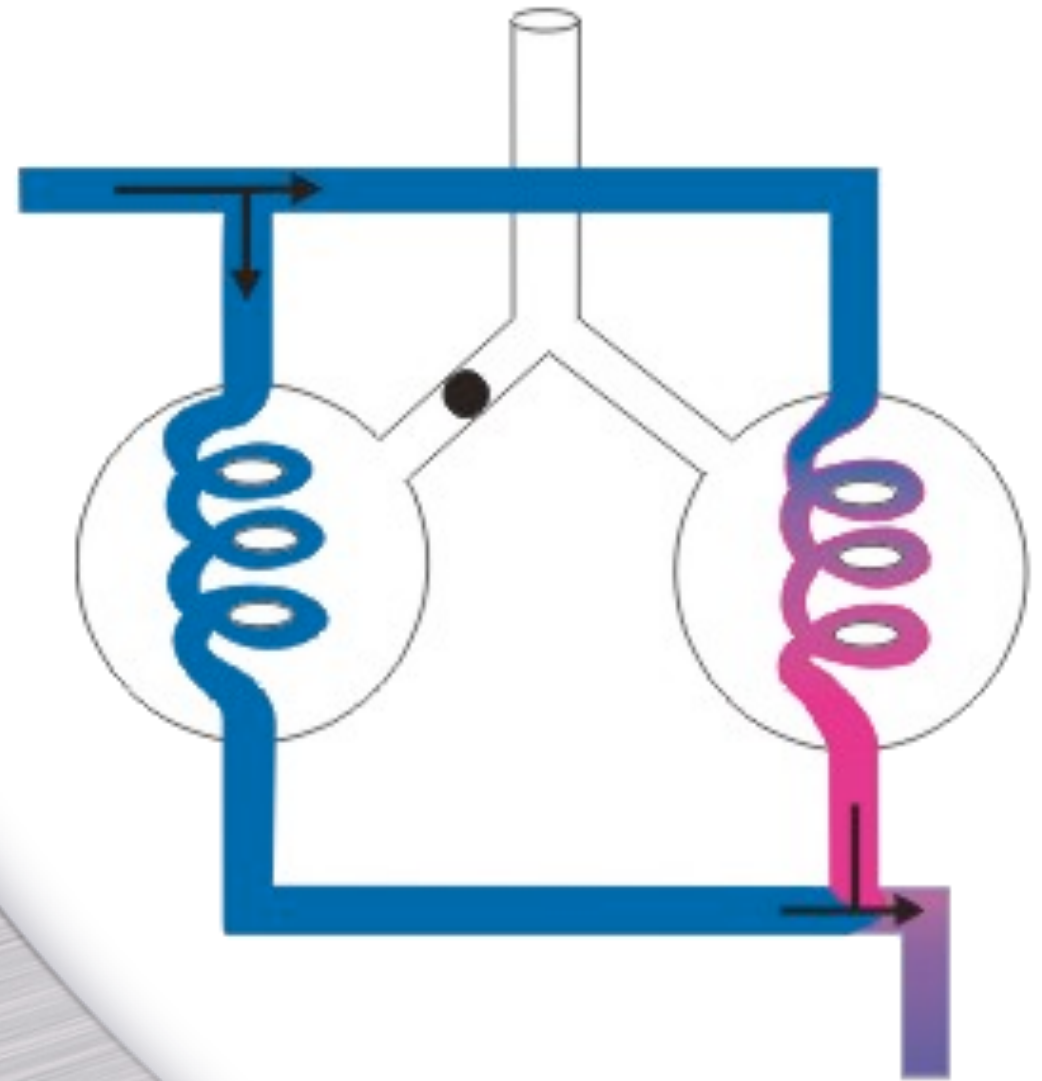

# Mixing of CO<sub>2</sub>

- The humidified air then mixes with carbon dioxide in the alveoli
- $PO_2 = 100 \text{ mmHg}$

# VQ matching & Shunt

- Not all alveoli are equal - some are better ventilated than others.
- Mixing of shunted blood leads to falls in  $O_2$  content

# Oxygen Cascade

- Normal inspired Oxygen is 160 mmHg
- Pressure falls by:
  - Humidification
  - Mixing with CO<sub>2</sub>
  - Diffusion
  - Shunt
- Normally 100 mmHg in Blood

# Physiology Examples

Maximal Ventilation  
Supplimental Oxygen  
Changes with Altitude

# Maximal Ventilation

- Hyperventilation reduces displacement by carbon dioxide in lungs
- Maximal hyperventilation ( $\text{CO}_2 = 15 \text{ mmHg}$ )
  - Water 10 mmHg,  $\text{CO}_2$  20 mmHg
- Maximum oxygen on air = 120 mmHg

## Supplimental Oxygen

- 100 % oxygen gives 760 mmHg partial pressure
- Displacement still occurs
  - Water 47 mmHg CO<sub>2</sub> 50 mmHg
- Maximum PO<sub>2</sub> on 100% oxygen
  - $760 - 47 - 50 = 663$  mmHg

## Mountain Climbing

- $P_{atm}$  halves each 5500m ascent
- At 5500m:
  - Atmospheric pressure 380 mmHg
  - Partial Pressure Oxygen 80 mmHg
  - If SVP  $H_2O$  is 47 and  $CO_2 = 40$ :
    - $PaO_2 = 80 - 10 - 50 = 20$  mmHg
  - If SVP  $H_2O$  is 47 and  $CO_2 = 16$ 
    - $PaO_2 = 80 - 10 - 20 = 50$  mmHg

## Estimating PaO<sub>2</sub>

- Maximum expected arterial oxygen level
  - About six times the FiO<sub>2</sub>
- Room air  $6 * 20 = 120$
- 100% oxygen  $6 * 100 = 600$
- Not a perfect rule, but an easy one.

## Summary

- Commonly used terms
  - Oxygen Partial Pressure
  - Oxygen Saturation
  - Oxygen Content
- Oxygen Carriage in blood
- Relationship of  $SaO_2$  to  $PaO_2$
- Oxygen Cascade
- Examples

# **Assessment of Oxygenation**

## What to look at.

- Oxygen Saturation ( $\text{SaO}_2$ )
- Oxygen Partial Pressure ( $\text{PaO}_2$ )
- Oxygen Carrying Capacity (Hb)

## Where to sample?

- Arterial Blood
  - Arterial Stab
  - Arterial Line
- Venous Blood
  - PA catheter
  - Blood from a vein isn't mixed

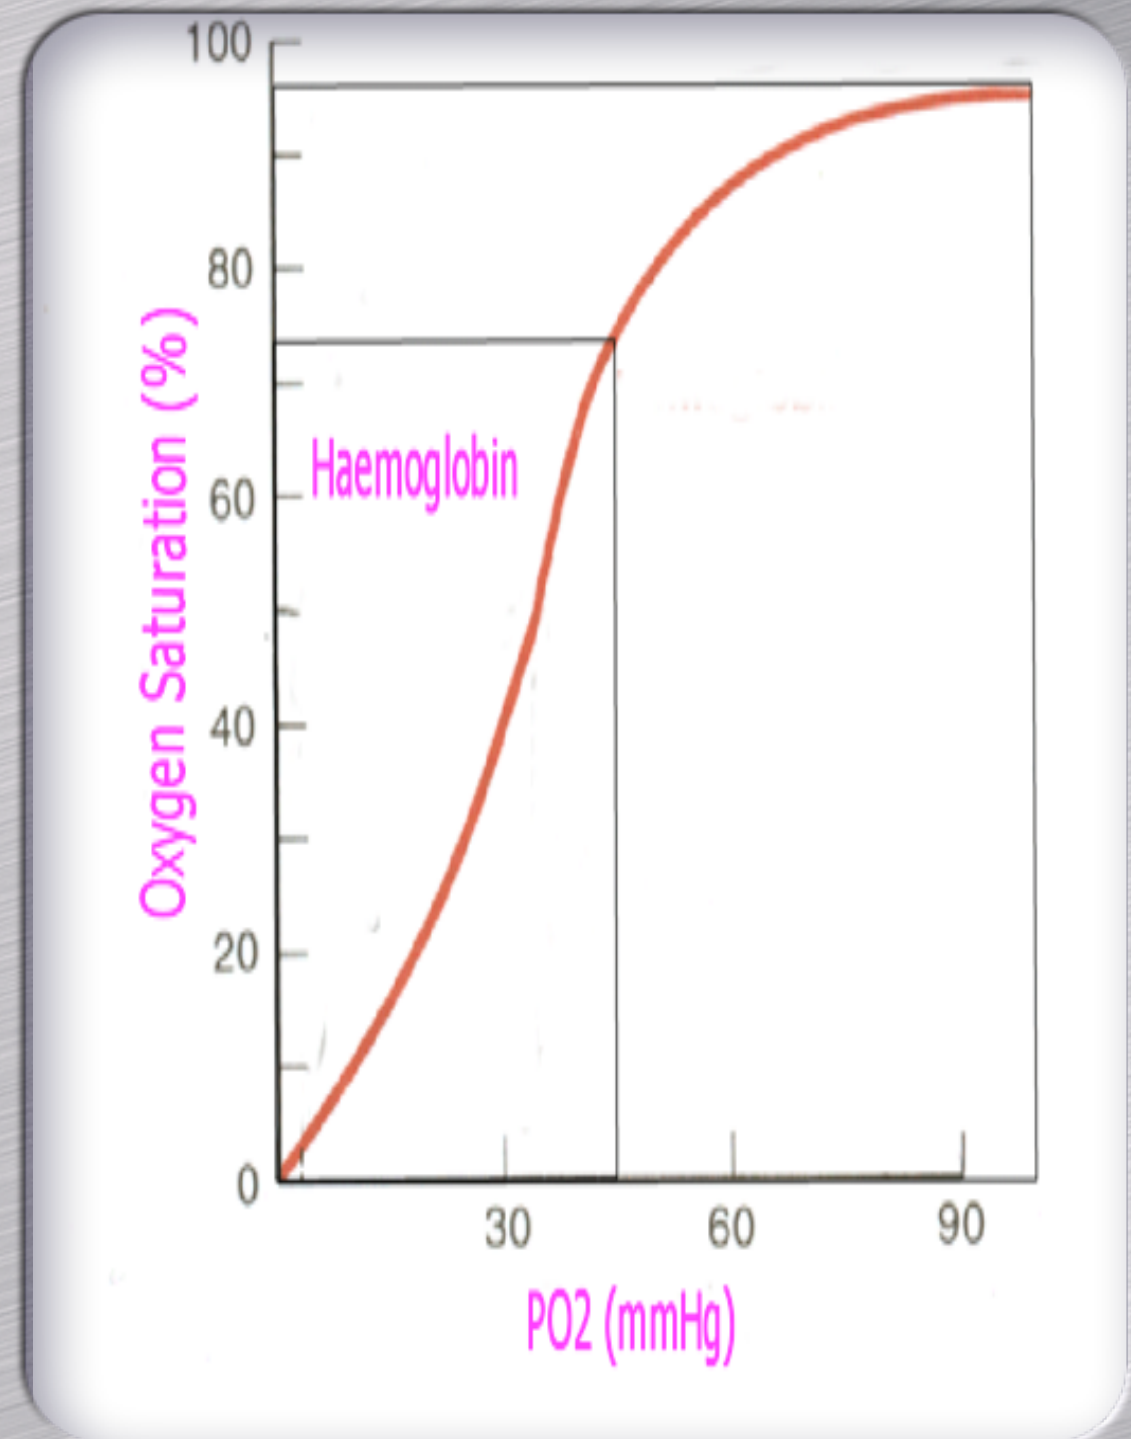

# Oxygen Flux

# Blood O<sub>2</sub> Levels

- Arterial Blood
  - PaO<sub>2</sub> – 100 mmHg
  - SaO<sub>2</sub> – 98%
  
- Venous Blood
  - PaO<sub>2</sub> – 40 mmHg
  - SvO<sub>2</sub> – 75%

# Oxygen Content

## Oxygen Content

- Content can be expressed mathematically

$$CaO_2 = SaO_2 \times Hb \times 1.34 + PaO_2 \times 0.03$$

- So the oxygen is mostly found on haemoglobin, not in the plasma.

# Blood O<sub>2</sub> content

- Arterial Blood Content: 200 ml/L
- Venous Blood Content: 150 ml/L
- 50 ml of oxygen is taken out of every litre of blood sent to the tissues.

# Oxygen Delivery & Return

# Normal $DO_2$ & $VO_2$

- Arterial blood 200 ml/L oxygen
- Venous blood 150 ml/L oxygen
- Cardiac output 5 L/min
  
- What is the normal amount of oxygen
  - Delivered to the tissues?
  - Returned from the tissues?
  - Used by the tissues?

# Oxygen Delivery

- Oxygen delivery to tissues
- Oxygen returned from the tissues
- Oxygen used by the tissues

# Oxygen Delivery

- Oxygen delivery to tissues
  - $200 \text{ ml/L} \times 5 \text{ L/min} = 1000 \text{ ml/min}$
- Oxygen returned from the tissues
- Oxygen used by the tissues

# Oxygen Return

- Oxygen delivery to tissues
- Oxygen returned from the tissues
  - $150 \text{ ml/L} \times 5 \text{ L/min} = 750 \text{ ml/min}$
- Oxygen used by the tissues

# Oxygen Uptake

- Oxygen delivery to tissues
- Oxygen returned from the tissues
- Oxygen used by the tissues
  - $(200 - 150) \text{ ml/L} \times 5 \text{ L/min} = 250 \text{ ml/min}$

# Summary

- Arterial and Venous Blood
  - Where to sample?
  - Normal Values
- Oxygen
  - Content in blood
  - Delivery and Return

# Critical Care Examples

- Common scenarios

- Emphysema

- Sepsis

- Low cardiac output

- Anaemia

- Remember

- Its all about oxygen delivery

- 250 ml/min is normal

**Example**

# Emphysema

## Example

- 72 year old male.
- Smokes 30/day for all his life
- Now presents short of breath

# Empphysema

## Measurements

- Output 5 L/min. Hb 190 g/L
- Arterial Gases
  - Saturation 80%
  - Pressure 50 mmHg
- Venous Gases
  - Saturation 60%
  - Pressure 31 mmHg

## Calculations

- Oxygen Delivered:
  - $205 \text{ mL/L} \times 5 \text{ L/min} = 1.02 \text{ L O}_2/\text{min}$
- Oxygen Returned
  - $154 \text{ mL/L} * 5 \text{ L/min} = 0.77 \text{ L O}_2/\text{min}$
- Oxygen Used
  - 250 ml oxygen per minute

## Conclusion

- Lung disease is associated with
  - Low saturations and oxygen pressures
  - Polycythaemia as compensation
  - Normal uptake

**Example**

# Sepsis

## Example

- 24 year old male – IV drug user
- Presents with fever, tachycardia and hypotension.
- Admitted to ICU, swan ganz inserted

# Sepsis

## Measurements

- Output 12 L/min. Hb 150 g/L
- Arterial Gases
  - Saturation 90%
  - Pressure 80 mmHg
- Venous Gases
  - Saturation 50%
  - Pressure 28 mmHg

# Sepsis

## Calculations

- Oxygen Delivered:
  - $180 \text{ mL/L} \times 12 \text{ L/min} = 2.1 \text{ L O}_2/\text{min}$
- Oxygen Returned
  - $100 \text{ mL/L} * 12 \text{ L/min} = 1.2 \text{ L O}_2/\text{min}$
- Oxygen Used
  - 900 ml oxygen per minute

# Sepsis

## Conclusion

- Sepsis is associated with
  - High cardiac outputs
  - Low mixed venous returns
  - High oxygen utilisation
- Low  $SaO_2$  with lung involvement

**Example**

# Low Output

## Low Output

- 55 year old man post AMI
- No other medical history
- Hypotensive and tachycardic

# Low Output

## Measurements

- CO 2.5 L/min Hb 150
- Arterial Gases
  - Saturation 97%
  - Pressure 100 mmHg
- Venous Gases
  - Saturation 50%
  - Pressure 29 mmHg

## Calculations

- Oxygen Delivered:
  - $195 \text{ mL/L} \times 2.5 \text{ L/min} = 500 \text{ mL O}_2/\text{min}$
- Oxygen Returned
  - $100 \text{ mL/L} * 2.5 \text{ L/min} = 250 \text{ L O}_2/\text{min}$
- Oxygen Used
  - 250 ml oxygen per minute

# Low Output

## Conclusion

- Low output states are associated with
  - Normal arterial saturation and content
- The venous side is abnormal
  - Low mixed venous saturation
- If you halve the cardiac output
  - Oxygen extraction doubles
  - Total oxygen delivery is maintained

**Example**

# Anaemia

## Example

- 25 year old woman post partum haemorrhage
- No other medical history
- Normotensive and tachycardic

# Anaemia

## Measurements

- CO 10 L/min Hb 37
- Arterial Gases
  - Saturation 97%
  - Pressure 100 mmHg
- Venous Gases
  - Saturation 50%
  - Pressure 29 mmHg

# Anaemia

## Calculations

- Oxygen Delivered:
  - $50 \text{ mL/L} \times 10 \text{ L/min} = 500 \text{ mL O}_2/\text{min}$
- Oxygen Returned
  - $25 \text{ mL/L} * 10 \text{ L/min} = 250 \text{ L O}_2/\text{min}$
- Oxygen Used
  - 250 ml oxygen per minute

# Anaemia

## Conclusion

- Anaemia states are associated with
  - Normal arterial saturations but low content
- The venous side is abnormal
  - Low mixed venous saturation
  - Very low mixed venous content
- If you reduce oxygen content in blood
  - Output and extraction increase

# Critical Care Examples

- Common scenarios
  - Emphysema/Sepsis/Low output/Anaemia
- Low arterial saturations matter when extraction is high
  - Anaemia
  - Low output states
  - High O<sub>2</sub> demand (sepsis)

# Oxygenation Summary

- Physiology
- Assessment of oxygenation
- Oxygen Flux equations
- Examples
